(54) Title: LITHOGRAPHIC CONTACT ELEMENTS

(57) Abstract

A method of forming an interconnection, including a spring contact element, by lithographic techniques. In one embodiment, the method includes applying a masking material over a first portion of a substrate, the masking material having an opening which will define a first portion of a spring structure, depositing a structure material (e.g., conductive material) in the opening, and overfilling the opening with the structure material, removing a portion of the structure material, and removing a first portion of the masking material. In this embodiment, at least a portion of the first portion of the spring structure is freed of masking material. In one aspect of the invention, the method includes planarizing the masking material layer and structure material to remove a portion of the structure material. In another aspect, the spring structure formed includes one of a post portion, a beam portion, and a tip structure portion.

LITHOGRAPHIC CONTACT ELEMENTS

BACKGROUND OF THE INVENTION

Field of the Invention

The invention relates to an interconnection (contact) element suitable for effective pressure connections between electronic components.

Description of Related Art

Interconnection or contact elements may be used to connect devices of an electronic component or one electronic component to another electronic component. For example, a contact element may be used to connect two circuits of an integrated circuit chip or including an application specific integrated circuit (ASIC). Contact elements may also be used to connect the integrated circuit chip to a chip package suitable for mounting on a printed circuit board of a computer or other electronic device. Contact elements may further be used to connect the integrated circuit chip to a test device such as a probe card assembly or other printed circuit board (PCB) to test the chip.

Generally, interconnection or contact elements between electronic components can be classified into at least the two broad categories of "relatively permanent" and "readily demountable."

An example of a "relatively permanent" contact element is a wire bond. Once two electronic components are connected to one another by a bonding of a contact element to each electronic component, a process of unbonding must be used to separate the components. A wire bond contact element, such as between an integrated circuit chip or die and inner leads of a chip or package (or inner ends of lead frame fingers) typically utilizes a "relatively permanent" contact element.

One example of a "readily demountable" contact element is the contact element between rigid pins of one electronic component received by resilient socket elements of another electronic component. A second type of a "readily demountable" contact element is a contact element that itself is resilient or spring-like or mounted in or on a spring or resilient medium. An example of a contact element is a tungsten needle of a probe card component. The contact element of a probe card component is typically

intended to effect a temporary pressure connection between an electronic component to which the spring contact element is mounted and terminals of a second electronic component, such as a semiconductor device under test.

5 With regard to spring contact elements, generally, a certain minimum contact force is desired to effect reliable pressure contact to an electronic component (e.g., to terminals on electronic component). For example, a contact (load) force of approximately 15 grams (including as little as 2 grams or less and as much as 150 grams or more, per terminal) may be desired to effect a reliable electrical pressure connection to a terminal of an electronic component.

10 A second factor of interest with regard to spring contact elements is the shape and metallurgy of the portion of the spring contact element making pressure connection to the terminal of the electronic component. With respect to the tungsten needle as a spring contact element, for example, the contact end is limited by the metallurgy of the interconnection element (i.e., tungsten) and, as the tungsten needle becomes smaller in
15 diameter, it becomes commensurately more difficult to control or establish a desired shape at the contact end.

In certain instances, spring contact elements themselves are not resilient, but rather are supported by a resilient membrane. Membrane probes exemplify this situation, where a plurality of microbumps are disposed on a resilient membrane. Again,
20 the technology required to manufacture such contact elements limits the design choices for the shape and metallurgy of the contact portion of the contact elements.

Commonly-owned U.S. Patent Application No. 08/152,812 filed November 16, 1993 (now U.S. Patent No. 4,576,211, issued December 19, 1995), and its counterpart commonly-owned co-pending "divisional" U.S. Patent Application Nos. 08/457,479 filed
25 June 1, 1995 (status: pending) and 08/570,230 filed December 11, 1995 (status: pending), all by Khandros, disclose methods for making spring contact elements. In a preferred embodiment, these spring contact elements, which are particularly useful for micro-electronic applications, involve mounting an end of a flexible elongate core element (e.g., wire "stem" or "skeleton") to a terminal on an electronic component,
30 coating the flexible core element and adjacent surface of the terminal with a "shell" of one or more materials. One of skill in the art can select a combination of thickness, yield strength, and elastic modulus of the core and shell materials to provide satisfactory force-

to-deflection characteristics of the resulting spring contact elements. Exemplary materials for the core element include gold. Exemplary materials for the coating include nickel and its alloys. The resulting spring contact element is suitably used to effect pressure, or demountable, interconnections between two or more electronic components, including semiconductor devices.

Commonly-owned, co-pending U.S. Patent Application No. 08/340,144 filed November 15, 1994 and its corresponding PCT Patent Application No. PCT/US94/13373 filed November 16, 1994 (WO95/14314, published May 16, 1995), both by Khandros and Mathieu, disclose a number of applications for the aforementioned spring contact elements, and also disclose techniques for fabricating contact pads at the ends of the spring contact elements. For example, a plurality of negative projections or holes, which may be in the form of inverted pyramids ending in apexes, are formed in the surface of a sacrificial layer (substrate). These holes are then filled with a contact structure comprising layers of material such as gold or rhodium and nickel. A flexible elongate element is mounted to the resulting contact element structure and can be overcoated in the manner described hereinabove. In a final step, the sacrificial substrate is removed. The resulting spring contact element has a contact pad having controlled geometry (e.g., a sharp point) at its free end.

Commonly-owned, co-pending U.S. Patent Application No. 08/452,255 filed May 26, 1995 and its corresponding PCT Patent Application No. PCT/US95/14909 filed November 13, 1995 (WO96/17278, published June 6, 1996), both by Eldridge, Grube, Khandros and Mathieu, disclose additional techniques and metallurgies for fabricating contact tip structures on sacrificial substrates, as well as techniques for transferring a plurality of spring contact elements mounted thereto, en masse, to terminals of an electronic component.

Commonly-owned, co-pending U.S. Provisional Patent Application No. 60/005,189 filed May 17, 1996 and its corresponding PCT Patent Application No. PCT/US96/08107 filed May 24, 1996 (WO96/37332, published November 28, 1996), both by Eldridge, Khandros and Mathieu, disclose techniques whereby a plurality of contact tip structures are joined to a corresponding plurality of elongate contact elements that are already mounted to an electronic component. Also disclosed are techniques for fabricating "elongate" contact tip structures in the form of cantilevers. The cantilever tip

structures can be tapered, between one end thereof and an opposite end thereof. The cantilever tip structures are suitable for mounting to already-existing (i.e., previously fabricated) raised contact elements extending (e.g., free-standing) from corresponding terminals of an electronic component.

5 Commonly-owned, co-pending U.S. Patent Application No. 60/024,555 filed August 26, 1996, by Eldridge, Khandros and Mathieu, representatively discloses a technique whereby a plurality of elongate tip structures having different lengths than one another can be arranged so that their outer ends are disposed at a greater pitch than their inner ends. The inner, "contact" ends may be collinear with one another, for effecting
10 connections to electronic components having terminals disposed along a line, such as a center line of the component.

As electronic components get increasingly smaller and the spacing between terminals on the electronic components get increasingly tighter or the pitch gets increasingly finer, it becomes increasingly more difficult to fabricate interconnections
15 including spring contact elements suitable for making electrical connection to terminals of an electronic component. Co-pending and commonly-owned U.S. patent application Serial No. 08/802,054, titled "*Microelectronic Contact Structure, and Method of Making Same,*" discloses a method of making spring contact elements through lithographic techniques. In one embodiment, that application discloses forming a spring contact
20 element (including a spring contact element that is a cantilever beam) on a sacrificial substrate and then transferring and mounting the contact element to a terminal on an electronic component. In that disclosure, the spring contact element is formed in the substrate itself through etching techniques. In co-pending, commonly-owned U.S. patent application, Serial No. 08/852,152, titled "*Microelectronic Spring Contact Elements,*"
25 spring contact elements are formed on a substrate, including a substrate that is an electronic component, by depositing and patterning a plurality of masking layers to form an opening corresponding to a shape embodied for the spring contact element, depositing conductive material in the opening made by the patterned masking layers, and removing the masking layer to form the free-standing spring contact element.

30 Co-pending and commonly-owned U.S. patent application, Serial No. 09/023,859, titled "*Microelectronic Contact Structures and Methods of Making Same,*" describes a contact element having a base end portion (post component), a middle

portion (beam component) and a contact end portion (tip component) and methods separately forming each portion and joining the post portion together as desired on an electronic component.

5 What is needed is a method of fabricating interconnections suitable for present fine-pitch electrical connections that is scalable for future technologies. Also needed are improved methods of making contact elements particularly methods that are repeatable, consistent, and inexpensive.

SUMMARY OF THE INVENTION

10 A method of forming an interconnection, including a spring contact element, by lithographic techniques. In one embodiment, the method includes applying a masking material over a first portion of a substrate, the masking material having an opening which will define a first portion of a spring structure, depositing a structure material (e.g., conductive material) in the opening, and overfilling the opening with the structure material, removing a portion of the structure material, and removing a first portion of the
15 masking material. In this embodiment, at least a portion of the first portion of the spring structure is freed of masking material. In one aspect of the invention, the method includes planarizing the masking material layer and structure material to remove a portion of the structure material. In another aspect, the spring structure formed includes one of a post portion, a beam portion, and a tip structure portion.

20 The techniques presented herein may be used to form, for example, contact elements including spring contact elements on substrates including electronic components, such as ceramic- or semiconductor-based components. The contact elements may be formed, in whole or in part, directly on an electronic component or formed separately, as on a sacrificial substrate, and transferred to an electronic
25 component.

The method presented herein provides an improved method for fabricating a contact element. The use of lithographic techniques to fabricate the contact element is well-suited to the fine-pitch, close-tolerance world of micro-electronic components. The invention addresses and is particularly well-suited to making interconnections to
30 electronic components having their terminals (e.g., bond pads) disposed at a fine-pitch. As used herein, the term "fine-pitch" refers to electronic components that have their

terminals disposed at a spacing of at least less than 5 mils, such as 2.5 mils or 65 μm . As will be evident from the description that follows, this is preferably achieved by taking advantage of the close tolerances that readily can be realized by using lithographic rather than mechanical techniques to fabricate the contact elements. The incorporation of planarization steps into embodiments of the method of the invention permits multiple contact elements to be fabricated on a substrate with minimal tolerances. Thus, for example, a plurality of spring contact elements having a structure such as described above may be fabricated on or transferred to an electronic component such that each of their tip portions have a similar height and when contacted, for example, by a second electronic component, are displaced a similar distance. In this manner, the contact elements formed by the method of the invention offer more reliable contact height and contact force than prior art structures.

A contact element is also disclosed. In one aspect of the invention, the contact element is a resilient contact element or spring contact element in the form of a cantilever that includes an elongate beam portion extending about the first axis and having a surface that is substantially parallel to a second surface, a post portion coupled to a first surface and extending in a first direction by a second axis, and a tip portion coupled to a second surface and extending in a second direction above the second axis. The post portion is adapted to be coupled to an electronic component, such as to terminals on a ceramic- or a semiconductor-based electronic component. The beam portion forms a cantilever supported at one end to the post portion with the tip portion coupled to a second end.

The contact element of the invention is suitable for making either temporary or permanent electrical connection between terminals of electronic components such as a PCB and a chip under test. The contact element may be fabricated as a permanent element directly on an electronic component, such as a space transformer of a probe card assembly. Alternatively, the contact element of the invention may be separately fabricated on a sacrificial substrate and affixed at its post end, for example, by soldering to on electronic component.

For making temporary connection, the electronic component upon which the contact element is fabricated is brought together with another electronic component so that the tip end of the spring contact element is in pressure contact with a terminal of the

other electronic component. The contact element reacts resiliently to maintain contact pressure and any electrical connection between the two components.

For making permanent connections, the electronic component upon which the contact element is fabricated or affixed is brought together with another electronic component, and the tip end of the contact element is joined or bonded, such as by soldering or brazing or with a conductive adhesive, to a terminal of the other electronic component. In one embodiment, the contact element is compliant and may accommodate differential thermal expansion between the two electronic components.

As noted above, the contact element of the invention can be fabricated, along with a plurality of other contact elements, directly on the surface of a device, such as a semiconductor device, or on the surfaces of a plurality of semiconductor devices resident on a semiconductor wafer. In this manner, a plurality of devices resident on a semiconductor wafer can be "readied" for burn-in and/or test prior to being singulated from the semiconductor wafer. Alternatively, the contact element of the invention can be fabricated, typically with a plurality of other contact elements, on a sacrificial substrate and transferred to an electronic component.

Other embodiments, features, and advantages of the invention will become apparent in light of the following description thereof.

BRIEF DESCRIPTION OF THE DRAWINGS

The features, aspects, and advantages of the invention will become more thoroughly apparent from the following detailed description, appended claims, and accompanying drawings in which:

DETAILED DESCRIPTION OF THE INVENTION

The invention relates to a method of forming an interconnection element, including a contact element, by lithographic techniques. The invention offers an improved technique for fabricating contact elements, particularly for use in
5 interconnecting micro-electronic components. The invention also relates to a contact element. According to one aspect of the invention, the limits on size and pitch of the contact element of the invention or formed by the method of the invention are a factor of photolithographic techniques. By incorporating planarization steps as part of the photolithographic techniques, the invention contemplates the consistent formation of
10 contact elements, including cantilever spring contact elements, of similar size and mechanical (e.g., displacement) properties.

Suitable electronic components include, but are not limited to, an active semiconductor device, a memory chip, a portion of a semiconductor wafer, space transformer, a probe card, a chip carrier, and a socket. The electronic component may be
15 an active device or a passive device that supports one or more electronic connections. Independent fabrication also avoids the exposure of the electronic component to the process conditions associated with forming the contact-element.

The contact element or elements of the invention may be fabricated on or independent of the electronic component to which it is or they are joined. In the case of
20 independent fabrication, the invention permits the contact element or elements to be fabricated with a shape, size, and metallurgy that are not limited by the materials and layout considerations associated with the manufacture of the electronic component.

Disposed on an electronic component such as a space transformer of a probe card assembly, the contact elements of the invention are designed to accommodate contacts or
25 terminals of electronic components having minimal pitch or spacing tolerances. The contact elements may also adopt alternating orientation (e.g., left-right-left-right) so as to achieve a greater pitch between their post portion than at the tip portion. In another embodiment, the contact elements may adopt alternating lengths (e.g., short-long-short-long) so as to achieve a greater pitch between the post portion than at the tip portion of
30 adjacent contact elements. Similarly, alternating contact elements can be fabricated to have a greater pitch at their tip portions than their post portions. In summary, the contact

elements, whether fabricated on or independent of the electronic component to which they are joined may adopt a variety of orientations to accommodate various configurations associated with the electronic components to which they contact.

5 Figures 1a and 1b illustrate one embodiment of a contact element of the invention. Figure 1a shows contact element 10 comprising post portion 13, beam portion 14, and tip portion 16. Post portion 13 is disposed on terminal 11 of electronic component 9. Post portion 13 has a height of h_2 . Beam portion 14 is coupled at one end to post portion 13. Beam portion 14 has a height h_B , and length l_B . At the other end of beam portion 14 and coupled to a side opposite post portion 13 is tip portion 16. Tip
10 portion has a height h_1 .

 Figure 1b shows contact element 10 under load such as when accommodating a substrate under test. In this case, substrate 20 having terminal 21 is brought into contact with contact element 10 and a downward force, F , is applied at tip portion 16 of contact element 10 to deflect contact element 10 downward. In this embodiment, the length of
15 beam portion 14, L_B , determines the maximum overtravel of contact element 10. A suitable overtravel is, for example, 3-8 mils. To accommodate the suitable overtravel, the height of post portion 13, h_2 , should be greater than the height of tip portion 16, h_1 . In such instance, the greater height difference will minimize the possible "bottoming-out" of contact element 10 against the surface of electronic component 9. Figure 1(b)
20 shows deflected contact element 10 separated at its tip portion end by a height, h_3 . The height of post portion 13 may also be configured to be greater than the height of a capacitor or other structure that might be coupled to the surface of electronic component 9. Figure 1(a) shows capacitor 18 having a height, h_c , that is less than the height of post portion 13, h_2 .

25 Figure 1(b) also shows that the height of post portion 13 and the height of beam portion 14 ($h_2 + h_B$) further determines the overtravel of contact element 10 when the force, F , is applied by substrate 20. A "bottoming-out" of substrate 20 against the post portion end of beam portion 14 limits the maximum compression that may be applied to contact element 10 and serves, in one manner, to limit damage to contact element 10.

30 Under load such when contacting substrate 20, beam portion 14 deflects by an amount represented in Figure 1(b) by x . A spring constant may be calculated for this deflection as followed:

$$k = F/x.$$

In one embodiment, the spring constant k is proportional to the thickness of beam portion 14:

$$k \propto h_B^3.$$

- 5 Thus, based on the above relationship, controlling the thickness of beam portion 14 provides tight control of the spring constant. Controlling the spring constant for each contact element of an electronic component, such as the space transformer of a probe card assembly, allows a consistent contact force to be applied to each terminal, such a terminal 21 of a substrate under test (such as substrate 20).
- 10 Figures 2-13(c) illustrate a method of forming an interconnection that is a contact element on an electronic component in accordance with a first embodiment of the invention. A contact element that is a cantilever having a post portion, a beam portion, and a tip portion will be formed in this embodiment. It is to be appreciated that at a given time, a number of contact elements can be formed on a substrate. The method
- 15 described below focuses on the formation of a single contact element. It is to be understood that the discussion applies equally well to the fabrication of a number of contact elements on a substrate, such as an electronic component at a given time. Typically, each of the contact elements fabricated on a substrate will have substantially similar characteristics (i.e., dimensions, shape, etc.). It is also appreciated, however, that
- 20 the characteristics of the contact elements of a substrate can be individually controlled and determined for given application requirements.

Figure 2 shows a cross-sectional side view of electronic component 100. Electronic component 100 is, for example, a space transformer of a probe card assembly or an integrated circuit. Electronic component 100 includes, for example,

25 semiconductor- or ceramic-based substrate 105 having contacts or terminals 110 and 115 on opposing surfaces of substrate 105. In the case of a commercially available ceramic-based electronic component 100, for example, electronic component 100 contains terminals 110 and 115 on opposing surfaces of substrate 105. Terminals 110 and 115 are connected, for example, through conductive circuit 120 running through electronic

30 component 100 such as, for example, a molybdenum or tungsten and molybdenum/tungsten circuit 120. Terminals 110 and 115 on substrate 105 are, for

example, copper (Cu), nickel (Ni), and gold (Au) terminals that may be suitable for connecting to a contact element formed through the deposition of a conductive material by, for example, soldering. In one example, the copper facilitates the electroplating process and is the upper layer. The nickel acts as a barrier between the gold and the copper. Figure 2 also shows shorting layer 117 on the underside surface of substrate 105. Shorting layer 117, such as for example, a titanium-tungsten (Ti-W) layer, serves, in this example, to short terminal 115 during the fabrication of contact elements on substrate 105. As will become evident from the description that follows, this shorting feature of shorting layer 117 can advantageously be employed to establish an appropriate potential for an electrolytic process (e.g., an electroplating process) for fabricating contact elements on substrate 105. Shorting layer 117 may be removed, for example, by a sputter or chemical etch process, once contact elements are formed on the opposing surface of substrate 105.

In the application where contact elements are to be formed by plating and there is no through-circuit extending through the substrates allowing a shorting layer to be formed on a backside of the substrate, a conductive layer such as a seed layer is generally needed to accomplish subsequent plating. Thus, in a first step of such a process, a conductive layer is deposited over the surface of substrate 105. A suitable conductive layer is, for example, a titanium, tungsten, or a titanium-tungsten (Ti-W) layer, conformally deposited over the surface of the substrate (105). In this manner, the "blanket" layer deposition will electrically short together all exposed terminals (110) on the surface of the substrate (105).

Figure 3 shows electronic component 100 of Figure 2 after the further processing step of depositing first masking material layer 125 over substrate 105. In one preferred embodiment, first masking material layer 125 is a photoresist that is spin coated on the surface of substrate 105 and patterned as known in the art.

As shown in Figure 3, first masking material 125 is deposited and patterned to include opening 122 extending through first masking material layer 125. Opening 122 may be located at a position that is directly over a portion of terminal 110 or, in some cases, may be located at a position that is remote from terminal 110. By locating openings (122) at a position remote from terminals (110), a plurality of contact elements can be fabricated on an electronic component with a layout that differs from that of the

terminals of the electronic component. One configuration, for example, is to position openings (122) so that contact elements built thereon will have their tip portions arranged in an area array comparable to a ball grid array. The openings can be connected to terminals on the electronic component arranged, for example, as peripheral pads. It may be advantageous to make the contact elements substantially identical without displacement from the terminals (110). In this instance, it is useful to locate openings (122) in an area array corresponding to the array of the tip portions of the contact elements.

The side walls of first masking material layer 125 about opening 122 may be tapered so that opening 122 may be larger at the surface of first masking material layer 125 than at conductive layer 112, i.e., a positive taper. Suitable taper angles include, but are not limited to, 60°-90°. One having ordinary skill in the art will readily understand how to form the tapered opening in first masking material layer 125. It is to be appreciated that opening 122 can be formed in any suitable manner and may be stepped like an inverted, stepped, truncated pyramid.

First masking material layer 125 is deposited to a thickness of the desired height of the post portion of a contact element, taken into consideration subsequent shaping (e.g., planarization) of the material that is to be the post portion. In other words, the thickness of first masking material layer 125, that will primarily determine the distance that the main body portion (i.e., beam portion and tip portion) is spaced away from the surface of the electronic component. In the example of a contact element where resiliency is desired, for example, the dimensions of the post portion, the beam portion, and the tip portion may be coordinated to maximize the contact force of the tip portion with, for example, a terminal of an electronic component, and minimize potential "bottoming out" of the deflected beam portion. Such coordination is discussed in detail above with reference to Figures 1(a)-1(b) and the accompanying text. For current technologies, a suitable height of first masking material layer 125 will be approximately 5-30 mils.

Figure 3 shows first masking material layer 125 having opening 122 adjacent terminal 110. It is to be appreciated that opening 122 may have a variety of shapes including, but not limited to, substantially rectangular, cylindrical, or pyramidal

(inverted) or conical such as by having a wider opening at the exposed surface at conductive layer 112.

Next, as shown in Figure 4, first conductive material 130 is deposited in opening 122 in first masking material layer 125 to terminal 110. Suitable deposition techniques, include, but are not limited to, electroplating, chemical vapor deposition (CVD), sputter deposition, and electroless plating. In one example, first conductive material 130 is deposited through an electroplating process. First conductive material 130 is, in this example, an electroplate alloy such as copper or a nickel alloy, such as nickel-cobalt. First, conductive material 130 is typically applied in the form of a commercially available electroplate solution or bath. Next, a current is applied between terminal 110 and an anode of an electroplating cell (not shown). Negative charge build-up on terminal 110 causes metal ions from the electroplating solution to be reduced to a metallic state, and hence first conductive material 130, such as, for example, nickel-cobalt, is deposited on terminal 110. In this example, first conductive material 130 is deposited to a thickness of at least the thickness of first masking material layer 125, and preferably deposited to a thickness greater than first masking material layer 125 (overplating).

Figure 5 shows substrate 100 after the further processing step of planarizing first conductive material 130 and first masking material layer 125 in accordance with an embodiment of the invention. The planarization is accomplished, for example, by a grinding procedure or a chemical-mechanical polish with a suitable slurry. A suitable slurry for a chemical-mechanical polish is, for example, a silicon dioxide, aluminum oxide, and cesium oxide in a pH-adjusted slurry.

The planarization step of Figure 5 defines the height of the post portion of a contact element coupled to the substrate 105. The planarization step provides dimensional control of the contact element by establishing a known height for the post portion of the contact element. As noted, the height of the post portion plays an important role in determining the contact force that the contact element will deliver to, for example, a terminal of an electronic component. The height of the post portion also plays a role in minimizing the "bottoming out" of the deflected beam portion. Thus, the ability to control the height of the post portion of the contact element is very advantageous.

The planarization step of the invention should also proceed to a suitable stopping point, such as, for example, a flatness of about 1 micron per centimeter (or 0.1 mils per inch). The tolerance among a plurality of contact elements on a substrate will vary with the application and may be determined by one having skill in the art. Preferred
5 tolerances of less than 5 microns per centimeter and preferably less than 2 microns per centimeter are contemplated.

Once the post portion of a contact element is formed, Figure 5 shows substrate 105 after the further processing step of rendering an area on the surface of first masking material layer 125 conductive such that the area can act as a suitable electrode for an
10 electroplating process. In one embodiment, a portion of an area over first masking material layer 125 is covered with a thin adhesion/seed layer of conductive metal or metal alloy 135 such as a titanium, a titanium-tungsten alloy layer, or a titanium/gold bilayer. Seed layer 135 may be deposited via a blanket deposition, such as a sputter deposition. For an electroplated nickel-cobalt layer, for example, a seed layer having a
15 thickness of about 5000 angstroms is suitably deposited by, for example, a blanket sputter deposition process over the surface of first masking material 125. Alternatively, seed layer 135 maybe deposited as a plurality of "traces," each trace corresponding to an area over first masking material layer 125 where the beam portion of the contact element is to be formed to serve, in one manner, as an electroform whereupon the beam portion
20 can be fabricated.

In yet another embodiment, a stencil (shadow mask) may be deposited over the surface of first masking material layer 125. The stencil typically will have a plurality of openings extending laterally from an area above corresponding post portions (indicated by first conductive material 130) to define areas form beam portions of the contact
25 elements. The stencil may suitably be a thin (e.g., about 2 mils thick) foil of stainless steel which may be punched or etched to have openings. The stencil can be any suitable material having any suitable thickness that will permit seed layer 135 to be deposited onto first masking material layer 125 in a pattern of conductive traces corresponding to the shapes of the openings in the stencil. With the stencil in place, seed layer 135 is
30 deposited, such as by sputtering, onto the exposed surface of first masking material layer 125. The stencil may then be removed.

The selecting of the material for first masking material layer 125 and process for deposition of seed layer 135 should be considered together. The masking material needs to be stable in the environment of the deposition method. For example, a typical positive photoresist material contains some solvent that may outgas under high vacuum condition. It is preferable in this instance to modify the material, for example, by baking or exposure to light in order to cross-link or otherwise rigidify the masking material. Polyimide is a useful masking material and will tolerate a sputtering environment without significant degradation. Deposition also can be by means of chemical vapor deposition (CVD) or e-beam processes. This require less vacuum than the sputtering. For these processes, traditional Novolac photoresist resins can be used, possibly with some moderate cross-linking. Another consideration is that any modification to the masking material to make it stable under vacuum may make it more difficult to remove later in the process. A suitable material and process can be selected by one skilled in the art. One particular process is to use Novolac photoresist, patterned as described above, then partially cross-linked by heating. Deposition of seed layer 135 is accomplished using CVD.

Next, as shown in Figure 6, an area over substrate 100 is covered with second masking material layer 140, again such as photoresist bearing in mind the considerations of using multiple masking materials in the presence of conductive layers. Second masking material layer 140 is patterned to expose area 132 over substrate 100 that defines an area for a beam portion of the contact element.

Figure 8 shows substrate 100 after the further processing step of depositing second conductive material 145 over the top surface of the substrate. In one embodiment, second conductive material 145 is deposited through an electroplating process with an electroplate alloy such as nickel-cobalt. In Figure 8, second conductive material 145 is deposited to a thickness greater than the thickness of second masking material layer 140. Second conductive material 145 serves as the beam portion of the contact element. It is to be appreciated that amount deposited and thus the thickness of second conductive material 145 will depend, in part, on the desired thickness of the beam portion.

As shown in Figure 9, after the deposition of second conductive material 145 over substrate 105, second conductive material 145 and second masking material layer

140 are planarized by way of a grinding process or a chemical-mechanical polish such as described above to form a beam portion of the contact element on substrate 105. As noted above, in the case of a cantilever spring contact element, the thickness of the beam portion is directly proportional to the spring constant ($k \propto h_B^3$). Planarization of second
5 conductive material 145 and second masking material 140 provides tight control of the thickness of the beam portion of the contact element (i.e., control of the thickness of second conductive material 145), thus allowing a determinable and consistent contact force to be applied by each contact element.

The above-described process of patterning a masking material layer, depositing a
10 seed layer, depositing a conductive material, and planarizing, may be repeated numerous times to build complex structures. Some examples will be discussed in detail later in this description.

Figures 10(a)-11(b) show various representative, useful configurations for a beam portion of a contact element formed on substrate 105. It is to be appreciated that there
15 may be various other configurations suitable for particular applications for the contact elements of the invention. Figures 10(a)-11(b) are to be viewed as representative of these various configurations.

Figure 10(a)-10(f) show top planar views of various configurations of the beam portion of a contact element formed on substrate 105 in an xy plane. Figure 10(a) shows
20 second conductive material 145a patterned into a beam portion over first conductive material 130 and extending laterally from an area over first conductive material 130 in a substantially rectangular fashion. Figure 10(b) shows a second configuration wherein second conductive material 145b is configured to have a taper in the y-direction ("y-taper") as second conductive material 145c laterally extends (in an x-direction) from an
25 area over the surface of first conductive material 130. This configuration more evenly distributes the stress on the contact element by reducing the size of the extremity of the beam portion (e.g., the cantilever) of the contact element. In Figure 10(b), a laterally extending portion of second conductive material 145b is depicted with substantially linear edges. It is to be appreciated that the edges need not be substantially linear but
30 may be curved such as, for example, in a concave manner.

Figure 10(c) shows a third configuration of the beam portion of a contact element in accordance with a first embodiment of the invention. In this configuration, second conductive material 145c extends laterally (in an x-direction) and transversely (in a y-direction) from post portion 130 to form a curved beam portion. Figures 10(d) and 10(e) show a fourth and a fifth configuration, respectively, where beam portion (of second conductive material 145d and 145e, respectively) extends laterally and transversely. The laterally and transversely extending beam portions may be desirable, for example, when fabricating contact elements to particularly minimize the pitch between adjacent contact elements. Figure 10(f) shows a sixth configuration of a beam portion wherein second conductive material 145f partially encircles post portion 130.

Figures 11(a) and 11(b) show fourth and fifth configurations of the beam portion of the contact element in accordance with a first embodiment of the invention in an xz plane. Figure 11(a) shows second conductive material 145g having a planar upper surface and a concave lower surface. Figure 11(b) shows second conductive material 145h having a planar lower surface and a linearly decreasing upper surface toward the extremity. Conductive materials 145g and 145h can be formed in this manner in a number of ways, including varying the light source to shape the underlying and adjacent photoresist that forms the masking material and electroplating in the presence of a non-conductive mask to distribute the electroplated material where desired.

Figures 12(a) and 12(b) show one aspect of the first embodiment of the invention. In this aspect, the fabrication of the components for the contact element on electronic component 105 by lithographic techniques is substantially complete with the formation of a spring contact element having a post portion of first conductive element 130 and a beam portion of second conductive material 145. Figure 12(a) shows substrate 100 after the further processing step of removing first masking material layer 125 and second masking material layer 140. In the example where a first masking material layer 125 and second masking material layer 140 are photoresist, a step of removing first masking material layer 125 and second masking material layer 140 may be accomplished with an oxygen plasma etch (e.g., oxygen ashing). Other methods of removing the masking material layers include, but are not limited to, laser ablation and wet chemical etching. An additional etch may be required to remove excess or undesired portions of seed layer 135. However, because seed layer 135 is typically thin (e.g., about 5000 Å), any excess or undesired seed layer material is typically removed with the removal of the masking

layer material. In this manner, Figure 12(a) shows a free standing contact element affixed to electronic component 105 at terminal 110 and having a post portion represented by first conductive material 130 and a laterally and/or transversely extending beam portion represented by second conductive material 145. A structure such as this
5 may serve as a useful contact structure, for example, by coating some portion of the beam portion with a suitable contact material.

In one preferred example, a separately formed tip portion 1500 may be affixed to the distal end of the beam portion, for example, by brazing, soldering, welding (e.g., spot welding), conductive epoxy, tacking, etc. to form the contact element shown in
10 Figure 12(b). One method of forming a tip portion is described herein with reference to Figures 14-18(b) and the accompanying text. Other methods of forming and transferring tip portions are described in detail in commonly-owned U.S. Patent No. 5,829,128 and PCT Application No. PCT/US97/08606, published November 20, 1997 as WO97/43653. In PCT Application No. PCT/US97/08606, for example, a method is described for
15 fabricating a plurality of contact tip portions having a relatively precise positional relationship with one another on a sacrificial substrate such as a silicon wafer. The contact tip portions are readily fabricated on a sacrificial substrate to extremely close tolerances given conventional semiconductor processing techniques (e.g., photolithography, deposition, etc.), to prescribe a spatial relationship with one another.
20 So long as the contact tip structures remain resident on the sacrificial substrate, the tolerances in spatial relationship are preserved. The invention described in that co-pending application facilitates the construction of contact elements by joining a plurality of contact tip portions to a corresponding plurality of interconnection elements (e.g., beam portions of contact elements). The tip portions are joined to contact elements by
25 bringing the tip portions, still resident on the sacrificial substrate, in contact with the contact element and joined, for example, by brazing and then removing the sacrificial substrate. These techniques can be used to transfer the tip portion to the structure of Figure 12(a).

Figures 13(a)-13(c) show a second aspect of the first embodiment of the
30 invention wherein the tip portion of the contact element is fabricated on substrate 105 using further lithographic techniques. Figure 13(a) shows electronic component 100 after the further processing step of depositing third masking material layer 150 over substrate 105 and patterning opening 155 to second conductive material 145 at the distal

end of second conductive material 145 (i.e., distal relative to the location of first conductive material 130). Opening 155 has a diameter suitable for the formation of a desired tip portion of the contact element. A suitable opening is, for example, 6 mils in diameter. Rectangular and/or sloped openings may also be incorporated.

5 Figure 13(b) shows electronic component 100 after the further processing step of forming a tip portion of the contact element in opening 155 of third masking material layer 150. The tip portion of the spring contact element is made of third conductive material 160. In one embodiment, third conductive material 160 is a multilayer material formed through an electroplating process. For example, third conductive material 160
10 may consist of a layer of gold of approximately 1 mil, followed by an optional thin layer of a noble metal such as rhodium, followed by a layer of nickel having a thickness of approximately 1.0-1.5 mils.

It is desirable, in certain applications, to include an outer contact layer for ultimate contact with a second electronic component. This may be in the form of a layer
15 that is deposited at the end of constructing a tip structure. This layer is decidedly optional, depending on applications and design criteria. It may be plated on a finished structure such as the tip in Figure 13(b).

When desired, a layer of contact metal can be plated as a final layer on a contact structure. Palladium (Pd), palladium-cobalt (PdCo), gold (Au) (soft or hard gold) and
20 rhodium (Rh) are particularly useful. These materials, their properties, and deposition methods are known in the art of contact structures for electronics. A particularly preferred material is an alloy of palladium and cobalt (PdCo). A useful thickness may be about 0 to about 200 microinches (0 to 5 microns) but more can be used -- even tens of microns or more. In one alternative design, the entire contact structure layer is made of
25 this material. In a particularly preferred embodiment, some portion of the final contact structure layer is made of this material.

The upper or top surface of third conductive material 160 may be shaped such as shown in Figure 13(b), such as pointed to yield, for example, an inverted pyramidal feature, by a controlled etch of third conductive material 160.

30 Figure 13(c) shows electronic component 100 after the further processing step of removing first masking material layer 125, second masking material layer 140, and third

masking material layer 150 to yield a free standing contact element on substrate 105. In the embodiment where first masking material layer 125, second masking material layer 140, and third masking material layer 150 are each a photoresist, the masking material layers may be removed through an oxygen ashing process as noted above. Other
5 techniques, including but not limited to, laser ablation and wet chemical etching may also be applied to remove the masking material layers. Figure 13(c) shows free standing contact element 101 overlying substrate 105 and affixed to terminal 110 of substrate 105. At this time, any shorting layer (e.g., shorting layer 117) may be removed.

The above description presented the first embodiment of the process of the
10 invention whereby a contact element is fabricated directly on an electronic component such as a space transformer of a probe card assembly. A particularly useful substrate for an electronic component is a ceramic-based substrate. In one aspect of the invention, a ceramic-based electronic component is chosen, for example, having terminals to accommodate corresponding contact elements, formed by a process such as described, to
15 test, for example, multiple integrated circuit dice or chips at a time. Such an electronic component can easily have 1500 or more contacts (terminals). As noted above, the same method described to form a single contact element may be used to form the additional contact elements.

A second useful substrate for an electronic component is a semiconductor
20 substrate. Metal substrates may also be utilized. One advantage of a semiconductor-based technique is that it offers, in the case of, for example, "chip-size" electronic components, the ability to fabricate more electronic components having contact elements at a single time than a ceramic-based electronic component which conceivably can be limited to forming contact elements on the single ceramic-based electronic component.

As is evident in Figure 13(c), a plurality of contact elements such as elongate or
25 cantilever contact element 101 can be affixed to an electronic component having a plurality of terminals on a surface thereof. In this aspect of the embodiment, each contact element 101 has post portion 130, beam portion 145, and tip portion 160 opposite post portion 130, and is affixed at its post portion to a corresponding terminal of
30 electronic component 105. Tip portion 160 of each contact element extends above the surface of electronic component 105 through a position that is laterally and/or transversely offset from post portion 130 forming a free-standing, cantilever structure.

In one embodiment, contact element 101 is resilient and is a spring contact element. Contact element 101 has an "effective" height of "L1," this being the distance between the highest portion of tip portion 160 and the inward most position where post portion 130 is affixed to electronic component 105. The actual height, "h₁" represents the distance that the highest portion of tip portion 160 extends from electronic component 105. The distance between the underside of beam portion 145 and the surface of electronic component 105 is represented by "h₂" and represents the distance that contact element 101 can deflect in response to compressive forces applied at tip portion 160 thereof.

10 Figures 14-21(c) illustrate a second embodiment of fabricating a contact element according to the invention. Figure 14 shows structure 400 including substrate 410 that is a sacrificial substrate such as, for example, a semiconductor substrate. For illustration purposes, substrate 410 is oriented to show a finished contact element having the same orientation as the contact element(s) represented in Figures 1(a)-13(c).

15 Formed in a surface of substrate 410 is a pyramidly-shaped feature. Methods for forming a pyramidly-shaped feature are described in detail in commonly-owned pending PCT Application No. PCT/US97/08606, published November 20, 1997 as WO97/43653. In PCT Application No. PCT/US97/08606, a method is described whereby a pyramidly-shaped feature is formed by the patterning of a masking material having a preferably
20 square opening measuring approximately of 1-4 mils on a side over a semiconductor substrate. Next, the substrate is etched to form the pyramidly-shaped depression. In the case of certain silicon semiconductor substrates, silicon will tend to be self-limiting as the etching proceeds along the crystal plane, such as at approximately 54.74° for silicon. In other words, the depression will extend to a depth that is dictated by the size of the
25 mask opening and the nature of the substrate. For example, with square openings of 2.5 mils per side, the depth of the depression will be approximately 2 mils.

Other methods of forming pyramidly-shaped features are described in commonly-owned U.S. Patent No. 5,809,128 and co-pending and commonly-owned U.S. patent application, Serial No. 08/802,054, titled "*Microelectronic Contact Structure, and*
30 *Method of Making Same.*"

Overlying the surface of substrate 410 is release layer 425. Release layer 425 is, for example, a metal such as aluminum, deposited to a thickness of approximately 5000

angstroms (Å) using conventional deposition techniques. Overlying release layer 425 on the surface of substrate 410 is seed layer 430. Seed layer 430 is, for example, copper that facilitates a copper electroplating process. In one embodiment, seed layer 430 of copper is deposited to a thickness of approximately 5000 Å using conventional deposition techniques.

Figure 15 shows structure 400 after the further processing step of depositing and patterning first masking material layer 435 over substrate 410. First masking material layer 435 is, for example, a photoresist such as used in the embodiment described above with reference to Figures 2-13(d) and the accompanying text deposited to a thickness of the desired height of the tip portion of a contact element taking into consideration the possibility of planarizing a portion of first masking material layer 435 with tip portion material. First masking material layer 435 is patterned to have an opening over feature 420.

Next, as shown in Figure 16, first conductive material 440 is deposited in the opening in first masking layer 435. First conductive material 440 is, in this example, an electroplate alloy such as a nickel-cobalt alloy similar to the electroplate alloy described above with reference to the embodiment described with reference to Figures 2-13(d). As noted above with respect to the embodiment described in Figure 13(b) and the accompanying text, it may be desirable to include an outer contact layer. Thus, where desired, a layer of contact metal can be plated, for example, above release layer 425. Suitable materials include palladium (Pd), palladium-cobalt (PdCo), gold (Au), and rhodium (Rh). A particularly preferred material is PdCo deposited to a thickness of about 0 to 5 microns but more can be used-even tens of microns or more. In a second preferred embodiment, the entire contact element is made of this material. In another preferred embodiment, only the final contact structure layer is made of this material. In a particularly preferred embodiment, some portion of the final contact structure layer is made of this material.

In one embodiment, first conductive material 440 is deposited to a thickness of at least the height of first masking material layer 435 and preferably greater than such height (overplating).

Figure 17 shows structure 400 after the further processing step of planarizing first conductive material 440 and first masking layer 435 in accordance with an embodiment

of the invention. The planarization is accomplished, for example, by a grinding procedure or a chemical-mechanical polish with a suitable slurry such as described above with reference to Figure 5 and the accompanying text. The planarization step of Figure 17 defines the height of the tip portion of a contact element.

5 In a first aspect of the second embodiment of the invention, the tip portion of first conductive material 440 may be removed and separately affixed to a contact element, such as for example, the contact element containing a post portion and a beam portion formed on an electronic component in Figure 12(a) and brazed, soldered or otherwise combined with a tip portion as shown in Figure 12(b). Figure 18(a) shows structure 400
10 after the further processing step of removing first masking material layer 435. In the example where first masking material layer 435 is a photoresist, first masking material layer 435 may be removed by an oxygen ashing, laser ablation, or wet etching. Once first masking material layer 435 is removed, the tip portion of first conductive material 440 may be separated from substrate 410 at release layer 425. In the example where
15 release layer 425 is aluminum, first conductive material 440 may be removed from substrate 410 by dissolving release layer 425 using sodium hydroxide (NaOH) solution as known in the art. Other methods of separation including but not limited to chemical etching and heat may also be suitable.

Before the tip portion of first conductive material 440 is separated from substrate
20 410, the tip portion may be combined with a post portion and a beam portion as shown in Figure 18(b) by, for example, brazing, soldering, or welding. Figure 18(b) shows an example of contact element 4001 coupled to electronic component 4000. Contact element 4001 includes post portion 4650 coupled to terminal 4010 of electronic component 4000, beam portion 4550 and tip portion 440 secured to beam portion 4550.

25 Figure 19(a) shows a second aspect of the second embodiment of the invention. Starting from structure 400 as shown in Figure 17, Figure 19(a) shows structure 400 after the further processing step of rendering a portion of first masking material layer 435 conductive to define an electrode area for a beam portion of the contact element that is to be formed in an electroplating process. As noted above (see Figure 6 and the
30 accompanying text), there are other methods of forming a beam portion that are also suitable.

Figure 19(a) shows structure 400 after the further processing step of rendering an area on the surface of first masking material layer 435 conductive such that the area is suitable as an electrode for an electroplating process. In one embodiment, a portion of an area of first masking material layer 435 is covered with seed layer 445 of a conductive metal or a metal alloy such as titanium layer, titanium-tungsten alloy layer or a titanium or titanium-tungsten/gold bilayer. For an electroplated nickel/cobalt layer, for example, seed layer 445 has a thickness of approximately 5000 Å. As noted above with respect to Figure 6 and the accompanying text, seed layer 445 may be deposited as a blanket layer or selectively as traces.

Next, as shown in Figure 19(b), an area over structure 400 is covered with second masking material layer 450, again such as photoresist. Second masking material layer 450 is patterned to expose an area of seed layer 445 and define a beam portion of the contact element.

Figure 19(c) shows structure 400 after the further processing step of depositing second conductive material 455 over the top surface of the structure. In one embodiment, second conductive material 455 is deposited through an electroplating process with an electroplating alloy such as nickel-cobalt. In the preferred embodiment, second conductive material 455 is deposited to a thickness of at least the thickness of second masking material layer 450, and generally greater than the thickness of second masking material layer 450 (overplating).

As shown in Figure 19(d), after the deposition of second conductive material 455 over structure 400, second conductive material 445 and second masking material layer 450 are planarized by way of a grinding process or a chemical-mechanical polish such as described above to form a beam portion of the contact element on substrate 410, the beam portion having a known thickness defined by the planarization step. Reference is made at this point to Figures 10(a)-11(b) and the accompanying text that show various configurations for a beam portion of a contact element formed on an electronic component. It is to be appreciated that the same techniques may be used to form the beam portion having various configurations on sacrificial substrate 410.

Figures 20(a) and 20(b) show a third aspect of the second embodiment of the invention. In this aspect, the tip portion and beam portion of the contact element may be removed from sacrificial substrate 410 and affixed to a separately formed post portion on

an electronic component. To separate the tip portion of first conductive material 440 and beam portion of second conductive material 455, an oxygen plasma, laser ablation, or wet etch may be used to remove first masking material layer 435 and second masking material layer 450 in the example where first masking material layer 435 and second masking material layer 450 are photoresist. The technique chosen will generally remove the excess seed layer materials or these excesses may be removed separately as noted above.

First conductive material 440 may be separated at this point from sacrificial substrate 410 at release layer 425. In the example where release layer 425 is aluminum, one method of separating first conductive material 440 from sacrificial substrate 410 is by reacting release layer 425 with a NaOH solution. Figure 20(a) shows tip portion of first conductive material 440 and beam portion of second conductive material 455 to be separated from sacrificial substrate 410. Beam portion of second conductive material 455 is to be affixed to separately fabricated post portion 4650 that is coupled to electronic component 4010 at a terminal of electronic component 4010. Post portion 4650 may be formed directly on an electronic component by the techniques described with reference to Figures 2-4 and the accompanying text. Beam portion of second conductive material 455 may be affixed to post portion 4650 after but preferably before separating tip portion of first conductive material 440 from sacrificial substrate 410. Figure 20(b) shows the coupling such as, for example, by soldering, brazing, or welding.

Instead of separating a contact element containing a tip portion of first conductive material 440 and a beam portion of second conductive material 455 from sacrificial substrate 410, the second embodiment of the method of the invention alternatively contemplates the processing step of forming a post portion for the contact element. Figures 21(a)-21(c) illustrate this process.

Figure 21(a) shows structure 400 of Figure 19(d) after the further processing step of depositing seed layer 458 of a conductive metal or metal alloy, including, but not limited to, titanium or a titanium/gold bilayer.

Figure 21(a) also shows structure 400 after the further processing step of patterning third masking material layer 460 over structure 400 and patterning an opening to second conductive material 455 at the distal end of second conductive material 455 (i.e., distal relative to the location of first conductive material 440). Third masking

material layer 460 is, for example, a photoresist material similar to first masking material layer 435 and second masking material layer 450. Third masking material layer is patterned to a suitable height for a post portion of a contact element including consideration for a subsequent planarization step to define the height of the post portion.

5 A complete discussion of the height considerations for the post portion of a contact element is provided herein with reference to Figure 3 and the accompanying text.

Figure 21(b) shows structure 400 after the further processing step of depositing third conductive material 465 in the opening in third masking material layer 460, via, for example, an electroplate process. In one example, third conductive material 465 is nickel-cobalt similar to first conductive material 440 and second conductive material 455. Third conductive material 465 is preferably deposited to a thickness of at least the thickness of third masking material layer 460, and generally greater than the thickness of third masking material layer 460 (overplating). Figure 21(b) also shows structure 400 after the further processing step of planarizing third conductive material 465 and third masking material layer 460 to define a post portion of third conductive material 465 having a thickness defined by the planarization step.

10
15

In the example where first masking material layer 435, second masking material layer 450, and third masking material layer 460 are photoresist, an oxygen ashing, laser ablation, or wet chemical etch step is first used to remove the masking material layer. At this point, contact element 470 can be separated from sacrificial substrate 410 at release layer 425. In the example where release layer 425 is aluminum, the aluminum is reacted with, for example, a NaOH solution to separate contact element 470 from sacrificial substrate 410.

20

Figure 21(c) shows contact element 470 coupled to electronic component 480 such as the space transformer of a probe card assembly. Contact element 470 is coupled at its post portion (of third conductive material 465) to a terminal of electronic component 480 by, for example, soldering, brazing, welding, conductive epoxy, tacking, or other technique.

25

Contact element 470 of Figure 21(c) may be compared with contact element 469 of Figure 20(b). In Figure 20(b), beam portion 455 is secured to separately fabricated post portion 4650 by, for example, brazing or soldering. In Figure 21(c), contact element 470 is formed into a single unit including a post portion, a beam portion, and a tip

30

portion, by a series of deposition steps. In each case, the dimensions and the resiliency characteristics can be accurately controlled by utilizing lithographic techniques incorporating planarization steps.

Figure 22(a) illustrates a second and preferred technique for mounting a contact element fabricated on a sacrificial substrate to an electronic component. Figure 22(a) illustrates the technique where contact element 471 is fabricated on sacrificial substrate 410, for example, by the method described above with reference to Figures 14-21(b) and the accompanying text. Figure 22(a) shows contact element 471 coupled to sacrificial substrate 410 at its tip portion. The first masking material layer, second masking material layer and third masking material layer utilized to pattern the contact element has been removed. As shown in Figure 22(a), the post portion of contact element 471 is brought in the contact with a corresponding terminal 486 on electronic component 480, whereupon the post portion is suitably soldered, brazed, welded, etc., to terminal 486. It is to be appreciated that any suitable technique and/or material for affixing the post portion of contact element 471 to a terminal of an electronic component may be employed in each of the embodiments described above, including brazing, welding (e.g., spot welding) soldering, conductive epoxy, tacking the contact element in a suitable manner to the terminal and securely affixing the contact element to the terminal by plating (e.g., electroplating), and the like.

Once contact element 471 is affixed to electronic component 480, sacrificial substrate 410 is removed in a suitable manner such as those described hereinabove (e.g., chemical etching, heating, dissolution of the release layer, etc.), resulting in electronic component 480 having contact element 471 affixed thereto, as illustrated in Figure 22(b). As is evident in Figure 22(b), a plurality of elongate or cantilever contact elements such as described can be affixed to an electronic component having a plurality of terminals on a surface thereof. In this embodiment, each contact element has a post portion, a beam portion, and a tip portion opposite the post portion. Each contact element is affixed at its post portion to a corresponding terminal of the electronic component. The tip portion of each contact element extends above the surface of the electronic component through a position that is laterally and/or transversely offset from its post portion forming a free-standing, cantilever structure.

In one embodiment, the contact element is resilient and is a spring contact element. When affixed to an electronic component, the contact element of the invention has an "effective" height of deflection of "L2," this being the distance between the highest portion of the tip portion and the inward most position where the post portion is affixed to electronic component 480. The actual height "h₁" represents the distance that the highest portion of tip portion 160 extends from electronic component 480. The distance between the underside of the beam portion and the surface of electronic component 480 is represented by "h₂" and represents the distance that the contact element can deflect in response to compressive forces applied at the tip portion thereof (e.g., at the tip end feature).

Figure 23 illustrates an application for an embodiment of the contact element of the invention, specifically a resilient contact element or spring contact element. In Figure 23, contact elements 471 and 472 are affixed, for example, in the manner described with respect to Figure 13(c) or Figure 22(b) to a space transformer of probe card assembly so that tip portion ends 4711 and 4721 make pressure connections with terminals 492 of electronic component 490 such as a semiconductor device, or an area of a semiconductor wafer (not shown) containing a plurality of semiconductor devices.

Figure 24 illustrates an application wherein a plurality of contact elements 500 such as those described hereinabove are arranged on a substrate such as a space transformer of a probe card assembly and affixed thereto in the manner described hereinabove, so that their tip ends are disposed in a manner suitable for making contact with the bond pad of a semiconductor device having its terminals or bond pads arranged along its periphery. This application is similar to the application described in co-pending, commonly-owned U.S. patent application, Serial No. 08/802,054, titled "*Microelectronic Contact Structure, and Method of Making Same.*" In Figure 24, each contact element 500 includes post portion 502 and tip portion 504 and is mounted to an electronic component such as a space transformer (schematically illustrated by the dashed line 510) of a probe card assembly. Tip portion ends 504 are arranged in a pattern, mirroring the pattern of bond pads 522 (illustrated schematically by circles) of an electronic component (schematically illustrated by dashed line 520) such as a semiconductor device. Contact elements 500 "fan-out" from their tip portions 504, so that each of their post portions 502 is disposed at a greater pitch (spacing from one another) than their tip portions 504.

Figure 25 illustrates another application (also similarly described in co-pending, commonly-owned U.S. patent application, Serial No. 08/802,054 wherein a plurality of contact elements 600 such as those described hereinabove are arranged on a substrate such as a space transformer of a probe card assembly and affixed thereto in the manner described hereinabove, so that their tip portions are disposed in a manner suitable for making contact with the bond pads or terminals of a semiconductor device having its bond pads or terminals arranged in a row along a center line thereof. In Figure 25, each contact element, generally denoted by reference numeral 600, includes post portion 602 and tip portion 604, and are mounted to an electronic component such as a space transformer of a probe card assembly (schematically illustrated by dashed line 610). Tip portions 604 are arranged, in a pattern mirroring that of bond pad 622 (illustrated schematically by circles) of an electronic component (schematically illustrated by dashed line 620) such as a semiconductor device. Contact elements 600 are arranged in the following sequence. A first contact element 600a is relatively short (e.g., has the length in an x-direction of approximately 60 mils), and is disposed to extend towards one side (right, as used) of electronic component 620. A second contact element 600b is adjacent first contact element 600a and is also relatively short (e.g., a length in an x-direction of approximately 60 mils), and is disposed to extend towards an opposite side (left, as used) of electronic component 620. Third contact element 600c is adjacent second contact element 600b and is relatively long (e.g., has a length in an x-direction of 80 mils), and is disposed to extend towards the one side (right, as used) of electronic component 620. Finally, fourth contact element 600d is adjacent third contact element 600c and is also relatively long (e.g., has a length in an x-direction of 80 mils), and is disposed to extend towards the opposite side (left, as used) of electronic component 620. In this manner, tip portions 604 are disposed at a fine pitch commensurate with that of bond pad 622, and post end 602 are disposed at a significantly greater pitch from one another.

By using photolithographic techniques as described above, the contact elements according to the invention may be fabricated with minimal pitch. Accordingly, the contact elements according to the invention are well-suited to the fine-pitch, close-tolerance environment of micro-electronic components. Figures 26(a)-26(b) illustrate one layout where pitch between adjacent contact elements may be further minimized. Figure 26(a) and 26(b) show two different views of adjacent contact elements 740A and 740B. Adjacent contact elements 740A and 740B may be fabricated directly on an

electronic component according to the methods described above, particularly with respect to Figures 2-13(c). In this manner, each masking material layer will be patterned to form individual portions of adjacent contact elements. For example, with reference to Figure 3 hereinabove, first masking material layer 125 will be patterned, for example, with an opening for two post portions. First conductive material 130 will serve as the material for post portions 730A and 730B. Alternatively, contact elements 740A and 740B may be fabricated on a sacrificial substrate and transferred to an electronic component similar to the process steps above with respect to Figures 14-22(b) and the accompanying text.

10 Contact element 740A includes post portion 730A, beam portion 745A and tip portion 760A. As a further enhancement, contact element 740A also includes spacer portions 731A and 732A to separate, in this example, beam portion 745A of contact element 740A from underlying contact element 740B. In the manner where contact elements 740A and 740B are formed simultaneously, spacer portion 731A is patterned and formed at the same time as beam portion 745B of contact element 740B. Spacer portions in this embodiment are fabricated according to the techniques described for fabricating the post portions and beam portions of the contact elements (e.g., utilizing, in the first embodiment of the invention, a masking layer and mask having an opening, for example, over post portion 730A of contact element 740B and a second opening defining a beam portion for contact element 740B).

20 Contact element 740B includes post portion 730B, beam portion 745B and tip portion 760B. Contact element 740B further includes spacers 732B and 733B to align contact element 740B at a similar height (in a y-direction) as contact element 740A. In the manner where contact elements 740A and 740B are formed simultaneously, spacer portions 732A and 732B may be patterned in the same masking material layer (e.g., a third masking material layer in accordance with the ordering of the masking material layers with reference to Figures 2-13(c) and the accompanying text). Spacer portions 732A and 732B may then be formed of the same conductive material deposition (e.g., third conductive material 160 with reference to Figures 2-13(c) and the accompanying text). Similarly, spacer portion 733B of contact element 740A and beam portion 745A of contact element 740B may be patterned and formed simultaneously (e.g., of a fourth conductive material).

In this embodiment, using photolithographic techniques, the length of the rectangularly-shaped beam portions 745A and 745B of adjacent contact elements 740A and 740B may be varied. Adjacent contact elements 740A and 740B are fabricated along the same axis (e.g., x-axis) at their post portions (post portion 730A and 730B) and
5 along a second axis (e.g., z-axis) at their tip portions (tip portions 760A and 760B). As noted, beam portion 745A of contact element 740A is patterned directly over post portion 730B of contact element 740B. Accordingly, in an x-direction, the post portions (730A and 730B) are axially aligned. At the tip portion of each contact element (760A and 760B), contact elements 740A and 740B are axially aligned along a y-axis. Thus,
10 Figures 26(a) and 26(b) show adjacent contact elements that achieve a greater pitch between their tip portions and their post portions. Such a configuration is suitable, for example, to generate an electronic component with a plurality of contact elements for probing a second electronic component having its bond pads or terminals arranged along its periphery and having an ultra-fine pitch.

15 Figures 27(a)-27(b) describe a second orientation of adjacent contact elements according to an embodiment of the invention. Contact element 840A includes post portion 830A, beam portion 845A, and tip portion 860A. Contact element 840A also includes spacer portions 831A and 832A formed over post portion 830A. Spacer portions 831A and 832A, in this example, separate beam portion 845A from underlying
20 contact element 840B. Contact element 840B includes post portion 830B, beam portion 845B, and tip portion 860B. Contact element 840B further includes spacer portions 832B and 833B that align tip portion 860B with tip portion 860A of contact element 840A along a y-axis. In Figures 27(a) and 27(b), contact elements 840A and 840B are axially aligned at both their post portions and their tip portions.

25 Adjacent contact elements 840A and 840B shown in Figures 27(a) and 27(b) are axially aligned in both their post portions and their tip portions. Using photolithographic techniques, the rectangularly-shaped beam portion of each contact element is fabricated to approximately the same length and the resulting contact element is offset by the distance between the post portions along the same axis. Such a configuration is suitable,
30 for example, to generate an electronic component with a plurality of contact elements for probing a second electronic component having its bond pads or terminals arranged in an ultra-fine pitch row along a center line thereof.

Figures 28(C) and 28(b) illustrate still further arrangements using similar overlaying patterning techniques for forming contact elements as described with reference to Figures 26(a)-27(b). Figure 28(a) shows a plurality of contact element formed according to the techniques described hereinabove, arranged on an electronic component (not shown). Contact elements 900A, 900B, 900C, and 900D are arranged so that their corresponding tip portions 960A, 960B, 960C, and 960D, respectively, are aligned in a y-direction while base portions 930A, 930B, 930C, and 930D are staggered in an x-direction. Figure 28(b) shows a second configuration wherein a plurality of contact elements 980A, 980B, 980C, and 980D are arranged on an electronic component (not shown) so that their corresponding tip portions 985A, 985B, 985C, and 985D, respectively are staggered in an x-direction as are their corresponding base portions 990A, 990B, 990C, and 990D, respectively.

Figures 24-28(b) relate to layouts of electronic component utilizing a contact element of the invention. It is to be appreciated, that the examples described in Figures 24-28(b) are merely exemplary and that a plurality of other configurations, including contact elements having more than two different lengths disposed on a common component are contemplated. It is also to be appreciated that the techniques illustrated in Figures 24-28(b) may be used to generate an electronic component with a plurality of contact elements in any arrangement required for probing of either peripheral or lead-on-center (LOC) devices.

In the preceding detailed description, the invention is described with reference to specific embodiments thereof. It will, however, be evident that various modifications and changes may be made thereto without departing from the broader spirit and scope of the invention as set forth in the claims. The specification and drawings are, accordingly, to be regarded in an illustrative rather than a restrictive sense.

CLAIMS

What is claimed is:

1. In combination with an electronic component, a contact element, comprising:
a post component; and
a beam component joined to the post component, the beam component having a
5 first planarized surface.
2. The contact element of claim 1, wherein:
the beam component has a second planarized surface.
3. The contact element of claim 1, further comprising:
a layer of seed material deposited on and integrally connected to a first one of the
post component and the beam component.
4. The contact element of claim 3, further comprising:
the second one of the post component and the beam component deposited on and
integrally connected to the layer of seed material.
5. The contact element of claim 3, further comprising:
the layer of seed material being a seed layer.
6. The contact element of claim 3, further comprising:
the layer of seed material comprising multiple layers of seed material.
7. The contact element of claim 1, further comprising:
the post component having a planarized surface which is directly or indirectly
connected to the beam component.
8. The contact element of claim 1, further comprising:
the beam component having a first planar surface, a portion of which is directly
or indirectly connected to the post component.

9. The contact element of claim 1, further comprising:
the beam component having a first planarized surface which is opposite to a second surface of which a portion is directly or indirectly connected to the post component.
10. The contact element of claim 1, wherein:
the beam component is joined to the post component through one or more plated layers between the beam component and the post component.
11. The contact element of claim 1, further comprising:
a tip structure component joined to the beam component through one or more plated layers between the beam component and the tip structure component.
12. The contact element of claim 1, wherein:
the beam component is elongate, has a one end and an opposite end; and
the post component is joined to the one end of the beam component.
13. The contact element of claim 12, further comprising a tip component joined to the opposite end of the beam component.
14. The contact element of claim 13, wherein:
the beam component has a one surface and an opposite surface;
the post component is joined to the one surface of the beam component; and
the tip component is joined to the opposite surface of the beam component.
15. The contact element of claim 14, wherein the one surface of the beam component has been planarized.
16. The contact element of claim 1, wherein the post component is joined to an electronic component.

17. In combination with an electronic component, a contact element, comprising:
a tip structure component; and
a beam component joined to the tip structure component, the beam component having a first planarized surface.
18. The contact element of claim 17, wherein:
the beam component has a second planarized surface.
19. The contact element of claim 17, further comprising:
a layer of conductive material deposited on and integrally connected to a first one of the tip structure component and the beam component.
20. The contact element of claim 19, further comprising:
the second one of the tip structure component and the beam component deposited on and integrally connected to the layer of conductive material.
21. The contact element of claim 19, further comprising:
the layer of conductive material being a seed layer.
22. The contact element of claim 19, further comprising:
the layer of conductive material comprising multiple layers of conductive material.
23. The contact element of claim 17, further comprising:
the tip structure component having a planarized surface which is directly or indirectly connected to the beam component.
24. The contact element of claim 17, further comprising:
the beam component having a first planar surface, a portion of which is directly or indirectly connected to the tip structure component.

25. The contact element of claim 17, further comprising:
the beam component having a first planarized surface which is opposite to a second surface of which a portion is directly or indirectly connected to the tip structure component.
26. The contact element of claim 17, wherein:
the beam component is joined to the tip structure component through one or more plated layers between the beam component and the tip structure component.
27. The contact element of claim 17, further comprising:
a post component joined to the beam component through one or more plated layers between the beam component and the post component.
28. A method of creating a portion of a resilient contact structure, the method comprising:
applying a masking material over a first portion of a substrate, the masking material having an opening which will define a first portion of a spring structure;
depositing a structure material into the opening and overfilling the opening with the structure material;
removing a portion of the structure material; and
removing a first portion of the masking material, wherein at least a portion of the first portion of the spring structure is freed of the masking material.
29. A method as in claim 28, wherein the applying the masking material comprises:
applying the masking material and patterning the masking material to define the opening.
30. A method as in claim 29, further comprising:
prior to the step of depositing conductive material, seeding a seeding material onto at least a portion of the area of the second masking material.

31. A method as in claim 30, wherein:
the seeding material contributes to joining adjacent layers of conductive material.
32. A method as in claim 29, wherein the first portion of the resilient contact structure comprises one of (a) a post portion; (b) a beam portion; or (c) a tip structure portion.
33. A method as in claim 29, wherein the structure material is a conductive material and the resilient contact structure provides an electromechanical contact.
34. A method as in claim 33, wherein the first portion of the resilient contact structure flexes mechanically and conducts electrically when the resilient contact structure provides the electromechanical contact.
35. A method as in claim 29, wherein the removing of the portion of the structure material comprises removing at least the structure material which has overfilled the opening.
36. A method as in claim 35, wherein the removing of the portion of the structure material further comprises removing a second portion of the masking material.
37. A method as in claim 35, wherein the removing of the portion of the structure material comprises one of (a) grinding, (b) chemical mechanical polishing, and (c) etching.
38. A method as in claim 33, wherein the depositing comprises plating the conductive material into the opening.
39. A method as in claim 29, wherein the removing of the first portion of the masking material completely removes the masking material from the substrate.

40. A method of forming a contact element, comprising:
successively patterning a plurality of layers of masking material over a substrate, each layer of masking material having an opening;
depositing conductive material after each patterning step to form a contact element having:
a post component coupled to the substrate and formed in an opening in a first masking material layer,
a beam component coupled at a first location to the post component and extending from the post component and formed in an opening in a second masking material layer, and
removing the plurality of layers of masking material.
41. A method as in claim 40, further comprising depositing conductive material to form a tip component coupled to a second location of the beam component and formed in an opening in a third masking material layer.
42. A method as in claim 40, further comprising:
planarizing a surface of the conductive material and the first masking material layer after depositing conductive material.
43. A method as in claim 42, further comprising:
planarizing a surface of the conductive material and the second masking material layer after depositing conductive material.
44. A method as in claim 40, further comprising:
prior to the step of depositing conductive material, seeding a seeding material onto at least a portion of the area of the second masking material.
45. A method as in claim 44, wherein:
the seeding material contributes to joining adjacent layers of conductive material.

46. A method as in claim 40, wherein the substrate is an electronic component and the post component is coupled to a contact on the substrate.
47. A method as in claim 40, wherein the substrate is a first substrate and further comprising:
removing the contact element from the first substrate; and
affixing the contact element to a second substrate.
48. A method of fabricating a contact element comprising:
patterning a first masking material on a surface of a substrate to have a first opening over an area of the substrate;
depositing a first conductive material in the first opening;
planarizing a first surface of the first conductive material and the first masking material;
patterning a second masking material on the first surface having a second opening over the first conductive material;
planarizing a second surface of the second conductive material and the second masking material; and
removing the first masking material and the second masking material so that the remaining first conductive material and the second conductive material form a free-standing contact element extending from the surface of the substrate, the contact element having a post component that is secured to the area of the substrate and a beam component.
49. A method as in claim 48, wherein the second opening is patterned to extend from an area over at least a portion of the top surface of the first conductive material to an area that is offset from the top surface of the first conductive material, the offset having at least a component in the plane of the planarizing the first surface of the first conductive material.

50. A method as in claim 48, after planarizing a second surface:
patterning a third masking material on the second surface having a third opening over the second conductive material; and
planarizing a third surface of the third conductive material and the third masking material,
wherein the step of removing the masking material includes removing the third masking material.
51. A method as in claim 48, wherein the substrate is an electronic component and the post component is coupled to a contact on the substrate.
52. A method as in claim 48, wherein the substrate is a first substrate and further comprising:
removing the contact element from the first substrate; and
affixing the contact element to a second substrate.
53. A method of forming a contact element comprising:
successively patterning a first and a second layer of masking material over a substrate, each layer of masking material having an opening;
depositing a first conductive material after patterning the first layer of masking material but before patterning the second layer of masking material,
depositing a second conductive material after patterning the second layer of masking material, and
removing the plurality of layers of masking material to form an electromechanical contact element having:
a first portion formed in an opening in the first masking material layer,
a second portion coupled to the first portion and formed in an opening in the second masking material layer.
54. A method as in claim 53, further comprising:
planarizing a surface of the first conductive material and the first masking material layer after depositing the first conductive material.

55. A method as in claim 53, further comprising:
planarizing a surface of the second conductive material and the second masking material layer after depositing the second conductive material.

56. A method as in claim 53, wherein the electromechanical element forms a portion of a spring structure.

57. A method as in claim 54, wherein the substrate is a first substrate and further comprising:

removing the electromechanical contact element from the first substrate; and
affixing the electromechanical contact element to a second substrate.

5

58. A method of making electrical connections comprising:

10 patterning a plurality of spring contact elements on the surface of a first electronic component, each contact element having a post component coupled to the substrate, a beam component coupled at a first location to the post component, and a tip component coupled to a second location of the beam component, each of the post component, the beam component, and the tip component patterned successively over the substrate to form a free standing contact element; and

15 bringing the first electronic component together with a second electronic component so that the tip ends of the spring contact elements are in electrical contact with corresponding terminals on the second electronic component.

59. A method as in claim 58, patterning of the plurality of spring contact elements comprising one of fabricating the spring contact elements directly on the first electronic component and fabricating the spring contact elements on a second substrate and
20 transferring the fabricated spring contact elements to the first electronic component.
